---

an early drive back would be fine. Just didn't know if it would be feasible. Thanks so much!

scott

> Genetic variation is the lifeblood of any breeding program. However, the amount of variation within breeding pools is constrained by historical and recent genetic bottlenecks. For instance, in soybean it has been proposed that all North American breeding germplasm traces back to ~12 founder lines. This is superimposed on bottlenecks of domestication and adaptation. Using genomic tools we have measured genetic diversity in modern breeding lines, early domesticates and wild accessions for soybean and common bean. This is useful to understand the size of bottlenecks and subsequent admixture between genetic pools. The data can be used to make informed choices as to which genetic pools to use to begin to broaden the genetic base in breeding pools or to find useful genes to introgress. Even though the amount of genetic variation has been highly constrained in modern breeding pools, breeders have been able to continue to make significant gains in yield. It has been hypothesized that epigenetic and/or structural variation may play a role in these gains. We have been sequencing methylomes (methylated cytosines) for soybean and common bean as these methylated cytosines provide insights into epigenetic variation. We have found differences in epigenetic marks between soybean and common bean, due mostly to transposable element dynamics that distinguish the two genomes. Using structured populations and historical varieties, we are also finding epigenetic variation within breeding lines that may have played a role in their development. I will present data on the genetic history of soybean and common bean and variation in modern breeding pools.
